

Different types of exceptions in python?

Python has a rich hierarchy of built-in exceptions that represent different types of errors that can occur during program execution. All built-in exceptions are derived from the `Exception` class.

Here are some of the most common and important types of exceptions in Python:

1. `SyntaxError`:

- **What it means:** Occurs when the interpreter finds a grammatical mistake in your code, preventing it from understanding or parsing the code. This error usually happens *before* the program even starts running.
- **Example:** Forgetting a colon at the end of an if statement or having unmatched parentheses.

2. **IndentationError:**

- **What it means:** A type of `SyntaxError` that is specific to Python's strict use of indentation to define code blocks. It means your code's spacing is inconsistent or incorrect.
- **Example:** Mixing spaces and tabs, or incorrectly indenting a line within an `if` or `for` block.

3. **NameError:**

- **What it means:** Raised when you try to use a variable, function, or module name that hasn't been defined or properly imported in the current scope.
- **Example:** `print(my_undefined_variable)`

4. **TypeError:**

- **What it means:** Occurs when an operation or function is applied to an object of an inappropriate type.
- **Example:** Trying to add a number to a string (`5 + "hello"`) or calling a non-callable object.

5. **ValueError:**

- **What it means:** Raised when an operation receives an argument of the correct type, but an inappropriate value.
- **Example:** Trying to convert a non-numeric string to an integer (`int("hello")`) or using a value outside a valid range for a function.

6. **ZeroDivisionError:**

- **What it means:** Occurs when you try to divide a number by zero.
- **Example:** `10 / 0`

7. **IndexError:**

- **What it means:** Raised when you try to access an index that is outside the valid range of a sequence (like a list or tuple).
- **Example:** `my_list = [1, 2, 3]; print(my_list[5])`

8. **KeyError:**

- **What it means:** Raised when you try to access a dictionary key that doesn't exist.
- **Example:** `my_dict = {'a': 1}; print(my_dict['b'])`

9. **FileNotFoundError:**

- **What it means:** Raised when you try to open or access a file that does not exist at the specified path.
- **Example:** `open("non_existent_file.txt", "r")`

10. **AttributeError:**

- **What it means:** Occurs when you try to access an attribute (like a variable or method) that an object or class does not possess.
- **Example:** `my_string = "hello"; my_string.append('x')` (strings don't have an append method).
